Typhoon HIL DSP 180 Interface

Accelerate controller development with the plug-and-play TI DSP based HIL Interface. Pin-to-pin compatible with all Typhoon HIL emulators.
Testing made Simple.
Typhoon HIL DSP 180 Interface

Plug in a TI controller card and start controlling your power converter via a pin-to-pin compatible Typhoon HIL connection.

Applications

Typhoon HIL DSP 180 Interface built for a family of Texas Instruments C2000 control cards (F28377, F28379) is the way to go if you want to accelerate the development of power electronics applications. A plug-and-play, pin-to-pin compatible interface with Typhoon HIL family of real-time HIL emulators eliminates setup time and enables developers to focus on control code development in the comfort of their office.

Features and Benefits

- Directly connect the HIL DSP Interface to any Typhoon HIL emulator (no cables or external power supplies needed).
- Compatible with: Delfino F28377 and F28379 control cards.
- 64 TI control card pins connected to HIL.
- Measurement terminals for monitoring all DSP and HIL signals.
- JTAG connector.
- CAN bus.
- Optional external PSU for standalone use.

Plug-and-play HIL interface

Plug the HIL DSP Interface with a TI control card directly into your HIL emulator and start running your power electronics application from get go. Easily port any of Typhoon's and TI packaged control code examples directly into the DSP without worrying about interfaces (i.e. voltage levels and interface compatibility). All digital and analog signals from/to the HIL DSP Interface are routed directly to HIL analog and digital IO pins to TI controller side for any C2000 control card family.
Control system development.

A grid-tie inverter is an essential part of distributed generation units like wind turbines, photovoltaics, fuel cells, etc. They can control active and reactive power flows, inject current harmonics, etc. Additionally, ancillary control services like local voltage and frequency regulation, voltage harmonic compensation, or active filtering can also be obtained.

Test without limits

In HIL, grid voltage sources can be specified with arbitrary magnitude, frequency and phase shift values in just a few steps. Additionally, in runtime the user can program and reload grid voltage waveforms defined in order to emulate utility grid disturbances such as:
- voltage sags,
- spikes,
- phase angle jumps,
- magnitude ramp,
- frequency change, and
- harmonic distortion.

Indeed, the HIL approach enables the user to build and deploy completely safe “Megawatt” (MW) grid-connected inverter test installation at their office desk, without the need for expensive hardware test equipment and a high-power laboratory, which simultaneously eliminates all safety and cost issues of a laboratory setup. A developer can easily conduct standard controller tests required for grid-connected power electronics applications (i.e. BDEW, or the National Electric Code, IEEE 1547) and also non-standard test scenarios that might arise in real-life deployment. Typhoon HIL environment is distinguished from the traditional approach where expensive hardware test equipment like AC power sources for grid simulation are used. In addition, it allows engineers to focus on the evaluation of the software-based functionalities which are provided by the inverter’s controller, in order to satisfy most of the technical specifications for grid-connected converter systems.
